

## Townhouse Tribulation

Using the townhouse worksheet, determine the number of square feet of brick needed for...

- 1 townhouse
- 2 townhouses
- 3 townhouses
- 10 townhouses
- N townhouses

**Grade Levels 6 - 8**

## **Townhouse Tribulation**

Using the townhouse worksheet, determine the number of square feet of brick needed for...

1 townhouse  
2 townhouses  
3 townhouses  
10 townhouses  
N townhouses

### **Context**

This task was given to sixth grade students who had just finished a unit on functions and algebra. Students previously had studied the area of polygons.

### **What This Task Accomplishes**

This task allows students to find a rule for determining the number of sides connecting townhouses will have. It also provides them with a problem-solving situation to apply concepts and skills for finding areas of polygons.

### **Time Required for Task**

1-2 hours

### **Interdisciplinary Links**

This task brought up an interesting discussion on why townhouses or condominiums tend to be less expensive than building single-family homes. Students who live in townhouses shared that they know that only one wall exists between two townhouses in that they can usually hear everything that happens next door. So as you can see, this task can link to construction and the pros and cons of cutting corners, or in this case, walls.

### **Teaching Tips**

Students had a prior week of instruction on looking at patterns and creating function tables and rules based on the patterns. This provided students with some problem-solving skills with which to approach the task. Students who were not able to find an algebraic rule were still able to use logic to solve the problem. To make the task less complicated, you can provide the areas of one, two and three townhouses, but I wanted students to apply their prior knowledge of geometry so I could recheck for mastery.

## Suggested Materials

- Pencil
- Paper
- Calculators
- Townhouse worksheet (see page 4)
- Formula sheet (Some students needed to refer to this for finding the area of triangles.)

## Possible Solutions

- Area of three sides of townhouse =  $(25' \times 20') = 500 \times 3 = 1500$  square feet
- Area of front of townhouse =  $500 - 19.5$  (area of door and windows) = 480.5 square feet
- Area of roof peaks:  $(.5) (25') (20') = 250 \times 2$  peaks = 500 square feet
- Total area of one townhouse = 2480.5 square feet
- Two townhouses =  $2480.5 - 500$  for shared wall = 1980.5 square feet + first townhouse 2480.5 = 4461 square feet
- Three townhouses =  $2480 + 1950.5 + 1950.5 = 6441.5$  square feet
- Rule for any number of townhouses is  $1980.5N - 500 =$  square feet of bricks needed for any townhouses where  $N =$  number of townhouses.

## Benchmark Descriptors

### Novice

Few or no parts of the task are correct. Little math reasoning is used. Attempts at using math language may be present, but rudimentary.

### Apprentice

Some parts of the solution are correct, but the student is unable to correctly solve for  $N$  and 10. Representations are accurate for the student's solution. Some work is missing. Some correct math language is used.

### Practitioner

All work is shown. Math representations and language communicate the student's solution. Answers are correct for all parts. The approach used is clearly explained.

### Expert

All work is shown, labeled and organized. Math representations are used to solve and communicate the solution. The student shows/explains the derivation of the rule for  $N$  townhouses. Algebraic notation is used correctly. All parts of the solution are correct.

## Practitioner

Key =  = shingles  
 = bricks  
 = door  
 = window

Townhouse #1:

The 3 sides that are the same dimension add up to 1500 because they all have a measure of  $20' \times 25'$ . The side with the doors/windows is  $20' \times 25'$  but you have to subtract 19.5' because of the windows/door. The triangular part of the roof is  $20' \times 25'$  which equals 500'. You add all these answers together and it will come out as 2480.5 sq'.

Townhouse #2:

The 5 sides that have the same dimension add up to: 2500 sq'. The sides with the doors/windows is  $20' \times 25' \times 2 - 19.5'$ . This comes out to be 961 sq'. The triangular →

Correct work is shown throughout.

# Exemplars

## Practitioner

parts of the roof all equal 500 so multiply by 4 so: 1000 sq'. When you add all these together, it comes out as 4461 sq'.

Townhouse #3:

The 7 sides that all have the same dimension equal 3,500 sq'. The sides with the doors windows is 20'x25'x3-19.5' which equals 1441.5'. The triangular parts are added up to: 1500 sq'. When you add 24 these together, it comes out as 6441.5 sq'.

N and 10 townhouses:

You would figure N by finding the difference between each number of square footage in bricks. You will find the differences <sup>and answers</sup> on the separate paper. When you find N you can find 10 townhouses. Connection on other page too.

The student explains the approach used to solve the problem.

### ⑥ Write-up

First, I figured out the dimensions of the walls for 1 townhouse. I found the square footage for 1 wall, then found the square footage for three walls and for the last wall I subtracted the area of the doors and windows. I did the same for the roof and added them together. Next, for 'Visual N' I drew pictures of the townhouses. Since there is only one wall in between two townhouses, each townhouse would be missing a right wall. The left wall of the second townhouse would be the right wall of the first. All that you would have to do is this add with a right wall on at the end. I prove this with the math below.

The student achieves correct answers to all parts of the problem.

Algebraic notation is used correctly.

drawing. In section E (Function Table) I put all the information I already used in to the graph. For N it was relatively simple because it was what I had in the proving of the picture times the square footage of one ~~th~~ part: of the house.
